FACILITY: VAX-11 SORT/MERGE PDP-11 SORT/MERGE

ABSTRACT:

This module contains routines that process a user-defined collating sequence.

ENVIRONMENT: VAX/VMS user mode

AUTHOR: Peter D Gilbert, CREATION DATE: 20-Jan-1983

MODIFIED BY:

T03-001 Original
T03-002 Add a temporary fix to get a reasonable pad character if the pad character is ignored. PDG 26-Jan-1983
T03-003 Support ignored pad characters. Set ADJ to zero if there are ignored characters. PDG 28-Jan-1983
T03-004 Add COLL\$FOLD. PDG 31-Jan-1983
T03-005 Define CODE and PLIT psects. 1-feb-1983
T03-006 Change the interface to SOR\$\$COLLATE_x. PDG 7-Mar-1983
T03-007 Remove STATIC table stuff. Changes for PDP-11 compatability. PDG 5-Apr-1983
T03-008 Changes to simplify zapping the upper table. PDG 12-Apr-1983
T03-009 Store info in RES_REVERSE (not CS_REVERSE) in COLL\$RESULT.

Changed value of CS_K_REG for Bliss-11. PDG 15-Apr-1983 T03-010 Defined error statuses for Bliss-11. PDG 21-Apr-1983 T03-011 Add routine headers. PDG 5-Jul-1983 T03-012 Allocate large structures in the work area, not on the stack. PDG 25-Apr-1983 T03-013 Merge changes from Sort-11 and Sort-32 versions. 19-Sep-1983 T03-014 Allocate on the stack for Sort-32. Specify a comparison routine that can be used after an initial CMPC for Sort-32 PDG 14-Oct-1983	

CV

OVERVIEW:

The routines must be called in the following order:
INIT [BASE] [NEXT : MODIFY : FOLD]... RESULT
The routines PAD, TIE_BREAK and UPPER may be optionally called any time after the INIT and before the RESULT.

All characters are passed to these routines as a word length followed by zero, one or two characters (4 bytes max).
The routine INIT simply initializes all characters as ignored, the pad character as the null character, and no tie-breaking.

BASE defines a base collating sequence (via a 256 byte table). All 256 single-byte characters are given one-byte collating values. taken from the table.

NEXT specifies a character that is to get a single-byte collating value that collates larger than any other currently defined collating value.

OTHERS causes NEXT to be called for all currently ignored single-byte characters (similar to COBOL-style definitions).

MODIFY defines a character to collate just less than, equal to, or just greater than the (0,1,or 2 byte) collating value of a (0,1,or 2 byte) character string.

FOLD causes all lower case letters to be given the collating values of their upper case equivalents. If a double character that contain no lower case letters is defined, then lower case and mixed case double characters are defined to collate equal to this double character. for example,
This
'D\$'
'SD'
'Sd'
'Xy'
'XY'

causes these definitions ''d\$''=''D\$''
''\$d''=''\$d''

none

none none

none "xy"="XY","xY"="XY","Xy"="XY"

PAD defines the (single byte) pad character.

UPPER specifies a simple (i.e., like BASE), secondary collating sequence that should be applied if the primary collating sequence collates two strings as equal.

An entry in STAB is four bytes in length: <ch0.ch1.cv0.cv1>
The ch0.ch1 together form a single or double character.

The cv0.cv1 together form a single or double collating value,

CI

                                        FUNCTIONAL DESCRIPTION:
                                                fold characters (this is a shorthand for several calls to MODIFY). For each character (X) in the set of characters specified by BV_L, define it to collate equal to its change-case form (X xor (C). Also, for all double characters for which neither character is in BV_L, define the change-case forms to equal it.
                                        FORMAL PARAMETERS:
                                                 COLL_SEQ
                                                                          a two-longword array specifying the length/address
                                                                          of storage to use for the collating sequence.
                                                 BV_L
                                                                          the address of a 256-bit bitvector.

                                               To compress the range of collating values, we must determine what values are currently in use. In practice, we will determine which of the values 1..MAX_USED-1 are in use, and whether any larger values are in use. Unused values are freed, and larger values are decreased; repeat as needed. If more that 2*K_CHARS distinct values are in use, it would be almost impossible to "double-up" sufficent values to fit things in a byte, and certainly not by this code.

                                  ROUTINE COMPRESS_M: CS_LINK_0 =
  FUNCTIONAL DESCRIPTION:
                                              Convert the collating sequence to the efficient and succint form that's
                                              used by the comparison routines.
                                     FORMAL PARAMETERS:
                                              NONE
                                     IMPLICIT INPUTS:
                                              INIT must have already been called. CS is specified as a global register.
                                     IMPLICIT OUTPUTS:
                                              NONE
                                     ROUTINE VALUE:
                                              Status code
                                     SIDE EFFECTS:
                                              NONE
                                        BEGIN
                                        LOCAL
                                              BV:
                                                         BITVECTOR[MAX_USED],
                                              NEED.
                                              S:
                                                                                                        ! Status value
                                        CS_SETUP();
                                           We are going to mash this collating sequence down to size.
                                          first, check that the pad character isn't used in any double characters, and that it collates to a single byte collating value.
                                       FOR_ALL_DCHARS(ST)

IF .ST[ST_CHAR_0] EQL .CS[CS_PAD]

OR .ST[ST_CHAR_1] EQL .CS[CS_PAD] THEN RETURN COLLS_PAD;

END_ALL_DCHARS(ST);

IF .BBLOCK[CS[CS_PTAB_(.CS[CS_PAD])],COLL_C1] NEQ 0 THEN RETURN COLLS_PAD;
                                          Use fewer collating values
                                        S = COMPRESS(BV[0]);
IF_ERROR_( .S ) THEN RETURN .S;
```

                                    FUNCTIONAL DESCRIPTION:
                                            Dump the current (uncompressed) collating sequence definition.
                                    FORMAL PARAMETERS:
                                            ADJ
                                                       (optional) adjustment to be used when writing the '%X' form
                                                       of the primary table. For collating sequences with no ignored or double characters, this should be specified as -1, so that
                                                       the dump can be used in a compilation.
                                    IMPLICIT INPUTS:
                                            INIT must have already been called.
                                            CS is specified as a global register.
                                    IMPLICIT OUTPUTS:
                                            NONE

  Order the entries in the cs_stab table by the character codes. This is needed if there are several double characters with the
                                                     same first character. Note that the entry with the smallest value must be the first one accessed by the for_all_dchars macro. This code depends on the for_all_dchars macro accessing the entries in order from lower addresses to higher addresses.
